Optimal Portfolio Diversification in General Case

- Drop assumption of equal weighting, independence and equal variance
- Put x_i dollars in i th asset, $I=1,\dots,n$, where the x_i sum to \$1.
- Portfolio expected value $r = \sum_{i=1}^n x_i E(\text{return}_i) = \sum_{i=1}^n x_i r_i$
- Portfolio variance (two assets) =

$$x_1^2 \text{var}(\text{return}_1) + (1 - x_1)^2 \text{var}(\text{return}_2) + 2x_1(1 - x_1) \text{cov}(\text{return}_1, \text{return}_2)$$

Efficient Portfolio Frontier with Two Assets

- Frontier expresses portfolio standard deviation in terms of portfolio expected return r rather than in terms of x_1 .

- $$x_1 = \frac{r - r_2}{r_1 - r_2}$$

$$\begin{aligned} \sigma^2 &= \left(\frac{r - r_2}{r_1 - r_2}\right)^2 \sigma_1^2 + \left(\frac{r_1 - r}{r_1 - r_2}\right)^2 \sigma_2^2 \\ &+ 2 \frac{(r - r_2)(r_1 - r)}{(r_1 - r_2)^2} \sigma_{12} \end{aligned}$$

Open Yale courses

Portfolio Variance, Three Assets

- Portfolio variance =

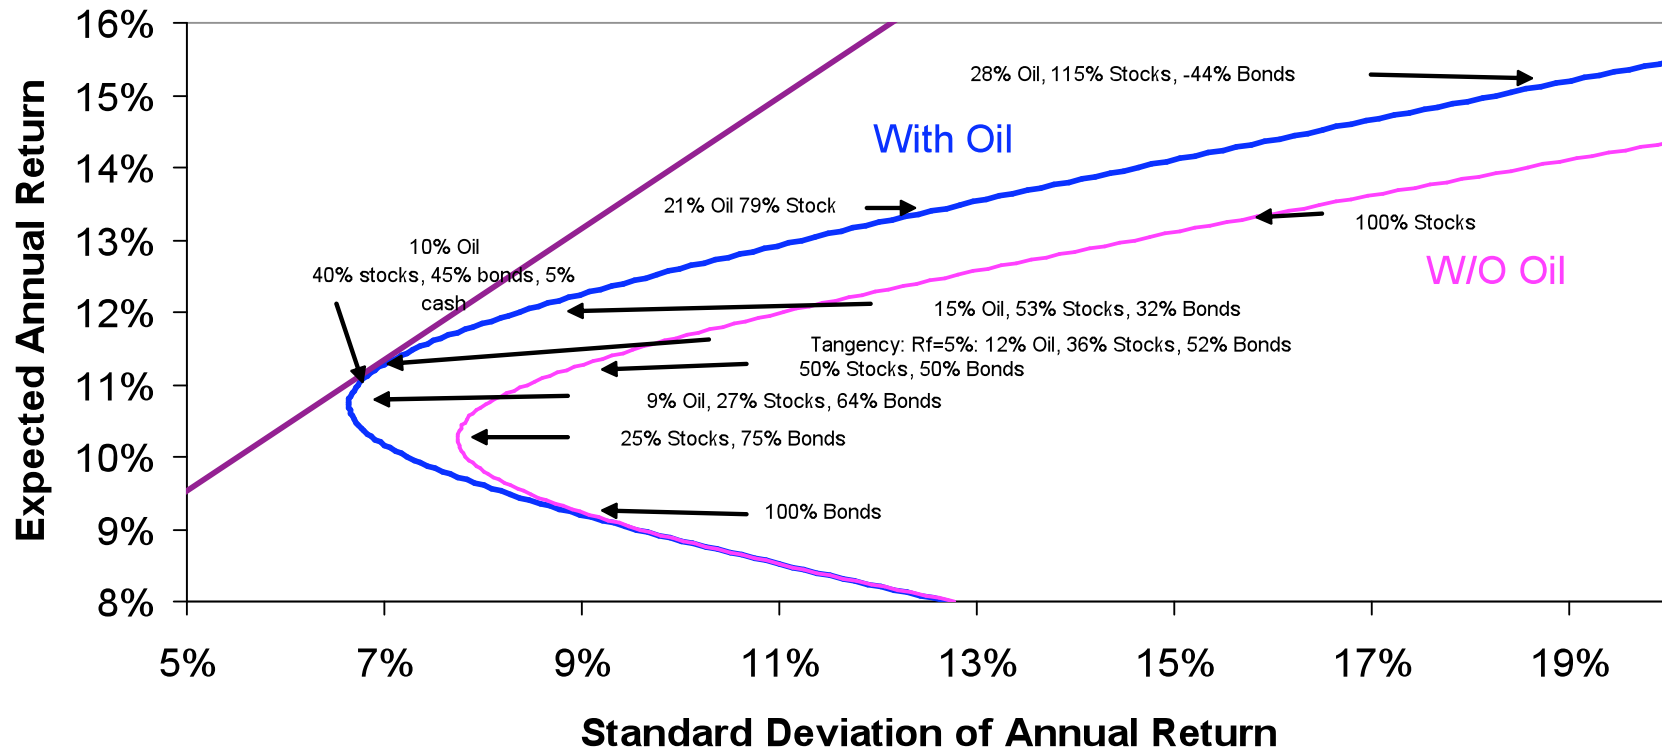

$$\begin{aligned} & x_1^2 \text{var}(\text{return}_1) + x_2^2 \text{var}(\text{return}_2) + x_3^2 \text{var}(\text{return}_3) \\ & + 2x_1x_2 \text{cov}(\text{return}_1, \text{return}_2) + 2x_1x_3 \text{cov}(\text{return}_1, \text{return}_3) \\ & + 2x_2x_3 \text{cov}(\text{return}_2, \text{return}_3) \end{aligned}$$

$$\text{(where } \sum_{i=1}^3 x_i = 1)$$

Beta

- The CAPM implies that the expected return on the i th asset is determined from its beta.
- Beta (β_i) is the regression slope coefficient when the return on the i th asset is regressed on the return on the market.
- Fundamental equation of the CAPM:

$$r_i = r_f + \beta_i (r_m - r_f)$$

US Corporate Taxes / Corporate Income (Income was negative 1932, 1933)

Survey of Individual Investors 1999

“Trying to time the market, to get out before it goes down and in before it goes up, is:

1. A smart thing to do; I can reasonably expect to be a success at it. 11%
2. Not a smart thing to do; I can't reasonably expect to be a success at it. 83%
3. No opinion 5%

Survey of Individual Investors 1999

“Trying to pick individual stocks, for example, if and when Ford Motor stock will go up, or IBM stock will go up, is:

1. A smart thing to do; I can reasonably expect to be a success at it. 40%
2. Not a smart thing to do; I can't reasonably expect to be a success at it. 51%
3. No opinion 8%

Survey of Individual Investors 1999

“Trying to pick mutual funds, trying to figure out which funds have experts who can themselves pick which stock will go up, is:

1. A smart thing to do; I can reasonably expect to be a success at it. 50%
2. Not a smart thing to do; I can't reasonably expect to be a success at it. 27%
3. No opinion 23%
